React Router

Applications have more than one page...

Fulvio Corno

Luigi De Russis

Enrico Masala

Outline

- Objective and problems
- A Solution, the React way: React Router

Full Stack React, chapter “Routing”

React Handbook, chapter “React Router”

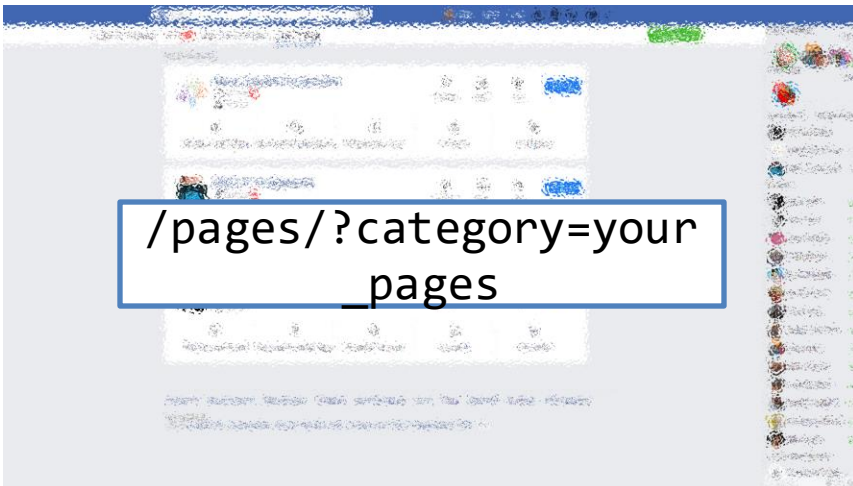

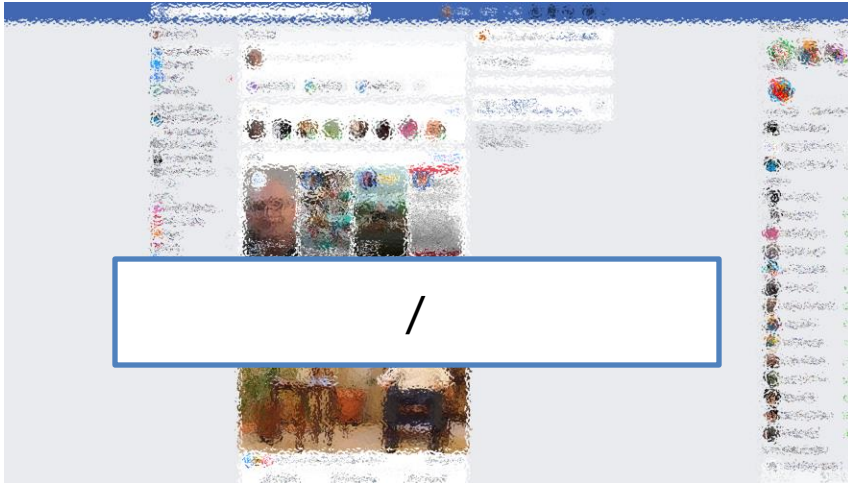

Multi-page Single Page Applications

OBJECTIVES AND PROBLEMS

Supporting Complex Web Applications

- Switching between many different page layouts
- Managing the flow of navigation across a set of “pages”
- Maintaining the default web navigation conventions (back, forward, bookmarks, ...)
- Allowing URLs to convey information
- Avoiding to re-load KBs of JavaScript at every page change
- Keeping the state across page changes
- ...

Example

- Different layout and contents
- Some common parts
- No “page reload”
- URL changes accordingly

Some Use Cases

- Main list / detail view
- Logged in / Unlogged pages
- Sidebar navigation
- Modal content
- Main Contents vs. User Profile vs. Settings vs. ...

Using URLs for Navigation State

- URLs determine the *type* of the page or the *section* of the website
 - Changing page \Leftrightarrow Changing the URL
- URLs also *embed information* about the item IDs, referrers, categories, filters, etc.
- **URLs can be shared/saved/bookmarked**, and they are sufficient for rebuilding the whole exact page
 - Deep Linking
- Back and Forward buttons navigate the URL history

Example URLs on facebook.com:

/

/profile.name

/profile.name
/posts/12341232124
22123

/pagename

/pages/?category=y
our_pages

Using URLs for Navigation State

- URLs determine the *type* of the page or the *section* of the website
 - Changing page \Leftrightarrow Changing the URL
- URLs also *embed information* about the item IDs, referrers, categories, etc.
- URLs can be *configured* to be sufficient for navigation
 - Deep Linking
- Back and Forward navigation

Special configuration:

- With any URL, the React application will **always return the same page** (`index.html/index.js`) that will load and mount the same App
- The URL content is then **queried by the App** to customize the render

Example URLs on facebook.com:

```
/
/profile.name
/profile.name
/posts/12341232124
22123
/pagename
/pages/?category=your_pages
```

React Handbook, chapter “React Router”

React as an HTTP Client

THE REACT ROUTER

React Router

- The problems associated with multi-page navigation and URL management are usually handled by *router* libraries
- A JavaScript Router manages
 - Modifying the location of the app (the URL)
 - Determining which React components should be rendered at a given URL location
- In principle, whenever the user clicks on a new URL
 - We prevent the browser from fetching the next page
 - We instruct the React app to switch in & out components

React Router

- React does not contain a specific router functionality
 - Different router libraries are available
- A commonly adopted one is **react-router**
 - Current version 7.x
 - `npm install react-router`

<https://reactrouter.com/>

<https://github.com/remix-run/react-router>

Features

- Connects React app navigation with the browser's native navigation features
- Selectively shows components according to the current routes
 - Rules matching URL fragments
- Easy to integrate and understand; it uses **normal React components**
 - Links to new pages are handled by `<Link>`, `<NavLink>`, and `<Navigate>`
 - To determine what must be rendered we use `<Route>` and `<Routes>`
 - Defines hooks `useRoute`, `useNavigate`, `useSearchParams`
- The **whole** application is **wrapped** in a `<BrowserRouter>` container

Overview of React-Router

`<Router>`

```
<Link to="/">Home</Link>
<Link to="/about">About</Link>
<Link to="/dash">Dashboard</Link>
```

`</Router>`

`'/about'`

`<Router>`

```
<Routes>
  <Route path="/"
    element={<Home />} />
  <Route path="/about">
    element={<About />} />
  <Route path="/dashboard">
    element={<Dashboard />} />
</Routes>
```

`</Router>`

Routers

- Routers can be initialized in three ways, or “modes”
 1. Declarative
 2. Data
 3. Framework
- Features available in each mode are *additive*
 - moving from Declarative to Data to Framework adds more features at the cost of architectural control
- In this course we will use the **Declarative** mode
 - enables basic routing features and fundamental APIs
 - allows to more clearly understand/control data loading procedures in components

Types of Routers in Declarative Mode

- `<BrowserRouter>` uses normal URLs and the HTML5 Location API
 - ➔ – **Recommended** for modern browsers
 - Requires *some server configuration*
 - `import { BrowserRouter } from 'react-router' ;`
- `<HashRouter>` uses '#' in the URL
 - Compatible with older browsers
 - Requires no config on the server
 - **Not recommended**, unless for compatibility reasons

Types of Routers in Declarative Mode

- `<BrowserRouter>` uses normal URLs and the HTML5 Location API

- **Recommended** for modern browsers
- Requires *some server configuration*
- `import { BrowserRouter } from 'react-router-dom'`

- `<HashRouter>` uses '#' in the URL

- Compatible with older browsers
- Requires no config on the server
- **Not recommended**, unless for compatibility

Not needed with the React Development Server.

When served as a static bundle, all paths must be mapped to index.html:

```
app.use(express.static('build'));

app.get('/*', function (req, res) {
  res.sendFile('build/index.html');
});
```

Not needed for this course

Wrapping `<App>` with a Router

```
import { StrictMode } from 'react';  
import { createRoot } from 'react-dom/client';  
import './index.css';  
import { BrowserRouter } from 'react-router';  
import App from './App.jsx';
```

```
createRoot(document.getElementById('root')).render(  
  <StrictMode>  
    <BrowserRouter>  
      <App />  
    </BrowserRouter>  
  </StrictMode>,  
)
```

Add the highlighted lines to main.jsx

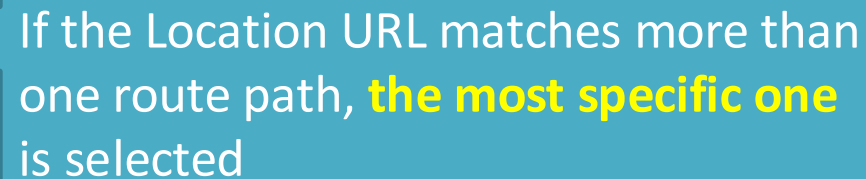

Selective Render

- Alternative versions of a component content must be wrapped in `<Routes>`
 - Each alternative is represented by a `Route`
 - The route with the “most specific” match will be rendered
- Each `<Route>` specifies the URL path matching requirement
 - `path = '/fragment'` check if the URL matches the fragment
 - `element = {<JSXelement/>}` renders the specified JSX fragment if the path is *the best match*

```
<Router>
  <Routes>
    <Route path="/" element={<Home/>} />
    <Route path="/news" element={<NewsFeed/>} />
  </Routes>
</Router>
```

Route matching Methods

- **path** = string matched against the URL
- A path is made of different URL 'segments' (separated by /)
 - **Static** segment → e.g., users
 - **Dynamic** segment → e.g., :userId
 - **Star** segment → *
- Examples:
 - /users/:userId
 - /docs/*
 - /
 - /contact-us
- Options
 - **caseSensitive**: the match becomes case-sensitive (default: insensitive)
 - changing the default is not recommended

If the Location URL matches more than one route path, **the most specific one** is selected

Nesting Routes

- Routes may follow the layout hierarchy of the interface components
- It is possible to **nest** a `<Route>` **inside** another `<Route>` component
 - The paths will be **concatenated**
 - The parent `<Routes>` will browse, recursively, through all matching paths
 - **All** route elements in the **best matching path** will be rendered
- The matching children will be rendered inside the `<Outlet>` component in the parent's render tree
 - `<Outlet>` specifies “**where**” the matching children should be rendered
 -  If you forget `<Outlet>`, the children will *not* display

Example

```
function App() {  
  return (  
    <div>  
      <h1>Basic Example</h1>  
      <Routes>  
        <Route path="/" element={<Layout />}>  
          <Route path="about" element={<About />} />  
          <Route path="dashboard"  
            element={<Dashboard />} />  
        </Route>  
      </Routes>  
    </div>  
  );  
}
```

```
function Layout() {  
  return (  
    <div>  
      <nav>... main navigation menu ...</nav>  
      <hr />  
      <Outlet />  
    </div>  
  );  
}
```

```
function About() {  
  return (  
    <div>  
      <h2>About</h2>  
    </div>  
  );  
}
```

Special Routes (1/2)

- **Index** route
 - `<Route index element={<Home />} />`
 - A child route with **no path** that renders in the parent's outlet at the parent's URL
 - Use cases:
 - They match when a parent route matches but none of the other children match.
 - They are the default child route for a parent route.
 - They render when the user did not click one of the items in a navigation list yet.

Special Routes (2/2)

- **Layout** route
 - A route without path will always be matched
 - Useful to “wrap” with a common layout its children’s routes
- **“No Match”** route
 - Special case: `path="*"`
 - Will match only when no other routes do

Example

```
function App() {  
  return (  
    <div>  
      <h1>Basic Example</h1>  
      <Routes>  
        <Route path="/" element={<Layout />}>  
          <Route index element={<Home />} />  
          <Route path="about" element={<About />} />  
          <Route path="dashboard" element={<Dashboard />} />  
          <Route path="*" element={<NoMatch />} />  
        </Route>  
      </Routes>  
    </div>  
  );  
}
```

```
function Layout() {  
  return (  
    <div>  
      <nav>... main navigation menu ...</nav>  
      <hr />  
      <Outlet />  
    </div>  
  );  
}
```

```
function Home() {  
  return (  
    <div>  
      <h2>Home</h2>  
    </div>  
  );  
}
```

Navigation

- Changing the location URL will re-render the Router, and all Routes will be evaluated
- Two options:
 - `<Link to= >` creates a router-aware hyperlink (activated by user clicks)
 - `useNavigate()` returns a function to trigger navigation (useful inside event handlers)

Navigation

- Changing the location URL will re-render the Router, and all Routes will be evaluated
- Two options:
 - `<Link to= >` creates a router-aware hyperlink (activated by user clicks)
 - `useNavigate()` returns a function to trigger navigation (useful inside event handlers)

Heavily penalized
at the exam

⚠ Warning ⚠

Never use a “plain hyperlink” `<a>`

Never use a “form submission”

(without `useActionState`)

`<form action='...'>`

They will reload the whole application
(and destroy the current state)

This is **NOT ALLOWED** in a SPA

Examples

```
function Home() {  
  return (  
    <div>  
      <h1>Home</h1>  
      <nav>  
        <Link to="/">Home</Link>  
        {" "  
        <Link to="about">About</Link>  
      </nav>  
    </div>  
  );  
}
```

```
function Invoices() {  
  const navigate = useNavigate();  
  return (  
    <div>  
      <NewInvoiceForm  
        onSubmit={(event) => {  
          const newInvoice = create(event.target);  
          navigate(`/invoices/${newInvoice.id}`);  
        }}  
      />  
    </div>  
  );  
}
```

All paths are relative,
unless they start with /

Active Navigation

- When creating menus or navigation elements, it is useful to see which item is the currently selected one
- `<NavLink>` behaves like `<Link>`, but knows whether it is “active”
 - It adds the “`active`” class to the rendered link (to be customized with CSS)
 - You may create a **callback** in `className={}` that receives the `isActive` status and decides which class to apply
 - You may create a **callback** in `style={}` that receives the `isActive` status and decides which CSS style(s) to apply

Dynamic Routes

- Routes may have **parametric** segments, with the **:name** syntax in the path specification
 - `<Route path="/post/:id" element={<Post/>} />`
 - The 'id' part will be available to the element through the `useParams()` hook

```
<Route  
  path="/post/:id"  
  element={<Post/>} />
```

```
function Post(props) {  
  const {id} = useParams();  
  ...  
}
```

Dynamic Routes

- Routes may have **parametric** segments, with the **:name** syntax in the path specification
 - `<Route path="/post/:id" element={<Post/>} />`
 - The 'id' part will be available to the element through the **useParams()** hook

```
<Route  
  path="/post/:id"  
  element={<Post/>} />
```

- useParams returns an object of key/value pairs of the dynamic params from the current URL that were matched by the `<Route path>`, e.g. `{ id: ... }`
- Children routes inherit all params from their parent routes

```
function Post(props) {  
  const {id} = useParams();  
  ...  
}
```

Example

```
function App() {  
  return (  
    <Routes>  
      <Route  
        path="/invoices/:invoiceId"  
        element={<Invoice />}  
      />  
    </Routes>  
  );  
}
```

Matches a URL like
`/invoices/1234`

```
function Invoice() {  
  const { invoiceId } = useParams();  
  return <h1>Invoice {invoiceId}</h1>;  
}
```

```
function Invoice() {  
  const params = useParams();  
  return <h1>Invoice {params.invoiceId}</h1>;  
}
```

Location State: Passing Information Among Pages

- When navigating, it is possible to **pass** some **information** to the next page, thanks to the `location.state` BOM attribute
 - Alternative to dynamic URLs
- The value may be retrieved with `useLocation()` on the next page
 - **Beware:** objects are serialized as strings, **avoid passing 'complex' objects** (e.g., DO NOT pass `dayjs` objects)

```
const navigate = useNavigate() ;

// go to URL and send information
navigate( url, {state: userData} ) ;
```

```
<Link to={url}
      state={userData} >
  . . .
</Link>
```

```
const location = useLocation();
const userData = location.state;
```

Exploiting Search Parameters

- A URL may contain some “query search parameters”
 - `/products?sort=date&filter=valid`
- `useSearchParams()` allows you to read and modify the query string portion of the location
 - Returns the current version of the parameter, and a function to modify them
 - Similar to `useState`

```
const [searchParams, setSearchParams] =  
  useSearchParams();
```

- `searchParams` is a `URLSearchParams` object

<https://developer.mozilla.org/en-US/docs/Web/API/URL/searchParams>

You may access each parameter with
`searchParams.get('sort')`
`searchParams.get('filter')`

- `setSearchParams` receives an object of `{ key: value }` pairs that will replace the current parameters

Summary: react-router-dom

- Wrap main.jsx in `<BrowserRouter>`
- Routing and rendering:
 - `<Routes>`
 - `<Route path= element= />`
 - `<Outlet/>`
- Navigation:
 - `<Link to= >...</Link>`
 - `<NavLink to= >...</NavLink>`
 - `useNavigate()` or `<Navigate>`
- Parameters
 - `useParams()` for Dynamic Routes
 - `useSearchParams()` for URL query strings (after “?”)
 - `useLocation()` for retrieving location state (set by navigate)
